

39.

when process request a resource . and if the resources are not available at the time the process enters into waiting state . waiting process may not change its state because the resources they are requested are held by other process. This is called deadlock!

Conditions:-

Mutual exclusion:- Only one process must hold the resource at a time . If any other process request for the resources, the requesting process must be delayed until the resource has been released.

Hold and wait:- A process must be holding at least one resource and waiting to acquire additional ~~resources~~ resources that are currently being held by the other process.

No preemption:- Resources can't be preempted i.e., only the process holding the resources must release it after the process has completed its task.

Circular wait:- A set  $[P_0, P_1, \dots, P_n]$  of waiting process must exist such that  $P_0$  is waiting for a resources i.e held by  $P_1$ ,  $P_2$  is waiting for a resources i.e held by  $P_2$ ,  $P_{n-1}$  is waiting for resources held by process  $P_n$ .  $P_n$  is waiting for resources held by  $P_1$ .

3b.

	Allocation	Max	Available
P <sub>0</sub>	0 1 0	7 5 3	3 3 2
P <sub>1</sub>	2 0 0	3 2 2	
P <sub>2</sub>	3 0 2	9 0 2	
P <sub>3</sub>	2 1 1	2 2 2	
P <sub>4</sub>	0 0 2	4 3 3	

need = Max - allocation.

Need matrix,

	Need		
	A	B	C
P <sub>0</sub>	7	4	3
P <sub>1</sub>	1	2	2
P <sub>2</sub>	5	0	0
P <sub>3</sub>	0	1	1
P <sub>4</sub>	4	3	1

Applying the safety algorithm on the given system,

Step 1: Initialization.

work = 3 3 2

	P <sub>0</sub>	P <sub>1</sub>	P <sub>2</sub>	P <sub>3</sub>	P <sub>4</sub>
finish:	false	false	false	false	false

Step 2: for i = 0

finish[P<sub>0</sub>] = false and need [P<sub>0</sub>] <= work (4 3) <= (3 3 2) ~~false~~

So P<sub>0</sub> must wait.

Step 2: for i = 1

finish[P<sub>1</sub>] = false and need [P<sub>1</sub>] <= work (1 2 2) <= (3 3 2) True

Step 3: work = work + allocation [P<sub>1</sub>] = (3 3 2) + (2 0 0) = (5 3 2) ~~false~~

	P <sub>0</sub>	P <sub>1</sub>	P <sub>2</sub>	P <sub>3</sub>	P <sub>4</sub>
finish:	false	true	false	false	false

Step 2: for i = 2

finish[P<sub>2</sub>] = false and need [P<sub>2</sub>] <= work (5 3 2) <= (5 3 2) ~~false~~

So P<sub>2</sub> must wait.

Step 2: for  $i=3$

finish  $[P_3] = \text{false}$  & need  $[P_3] \leq \text{work} (011) \leq (533)$   
true

So  $P_3$  must be kept in safe sequence.

Step 3:

work = work + Allocation  $[P_3] = (533) + (211) = (743)$

finish = 

$P_0$	$P_1$	$P_2$	$P_3$	$P_4$
false	true	false	true	false

Step 2: for  $i=4$

finish  $[P_4] = \text{false}$  & need  $[P_4] \leq \text{work} (743) \leq (743)$   
true

So  $P_4$  must be kept in safe place.

Step 3:

work = work + Allocation  $[P_4] = (743) + (002) = (745)$

finish = 

$P_0$	$P_1$	$P_2$	$P_3$	$P_4$
false	true	false	true	true

Step 2: for  $i=0$

finish  $[P_0] = \text{false}$  and need  $[P_0] \leq \text{work} (745) \leq (745)$   
true

So  $P_0$  must be kept in safe place.

Step 3:

work = work + Allocation  $[P_0] = (745) + (010) = (755)$

finish = 

$P_0$	$P_1$	$P_2$	$P_3$	$P_4$
true	true	false	true	true

Step 2: for  $i=2$

finish  $[P_2] = \text{false}$  & need  $[P_2] \leq \text{work} (755) \leq (755)$   
true

So  $P_2$  must be kept in safe place.

Step 3:

work = work + Allocation  $[P_2] = (755) + (302) = (1057)$

finish = 

$P_0$	$P_1$	$P_2$	$P_3$	$P_4$
true	true	true	true	true

Step 4: finish  $P_i$ : true for  $0 \leq i < n$

Hence, the system is currently in a safe place.

The safe sequence is  $\langle P_1, P_3, P_4, P_0, P_2 \rangle$

conclusion: yes the system is currently in safe place.

10. A thread is a basic unit of CPU utilization. It consists of Thread ID, program counter, a stack & a set of registers.

### Multiple Threading Models:

#### Many to One Model

Here, Many user level threads are mapped to a single kernel thread. Thread management handled by thread library in user space, which is very efficient.

Only one thread user can access the kernel at a time, as there is only one kernel thread. Thus the threads are unable to run in the parallel on multiprocessors.

one to one model: It creates a separate kernel thread to handle each user thread. It overcomes problems like blocking system calls and the splitting of process across

multiple CPU's. The overhead of managing the one-to-one model is significant, involving more overhead & slowing down the system.

Many to many thread?

It multiplexes any number of user threads onto an equal or smaller number of kernel threads,

- user have no restrictions on number of threads created
- Blocking kernel system calls do not block entire process
- processes can be split across multiple processors.
- This is also called as two tier model.
- Supported by OS such as IRIX, UNIX, HP-UX,
